

CLASSIFICATION OF DATABASE MANAGEMENT SYSTEMS

**THE RELATIONAL DATA MODEL
AND
RELATIONAL DATABASE
CONSTRAINTS**

CLASSIFICATION OF DATABASE MANAGEMENT SYSTEMS

- ? Database management systems can be classified based on several criteria, such as the **data model, user numbers and database distribution.**

Classification Based on Data Model

- ? Relational Data Model
- ? Hierarchical Data Model
- ? Network Data Model
- ? Object-Oriented Data Model

- ? The **Relational Data Model** in Database Management Systems (DBMS) organizes data into tables (relations), each consisting of rows (tuples) and columns (attributes).
- ? It uses primary keys to uniquely identify records and foreign keys to establish relationships between tables.
- ? This model ensures data integrity through constraints like primary keys, foreign keys, and unique constraints.
- ? Well-known DBMSs like **Oracle**, **MS SQL Server**, **DB2** and **MySQL** support this model.

- ? The **Hierarchical Data Model** is a way of organizing data in a tree-like structure.
- ? Each node represents a record (or entity), and the edges represent relationships between the records.
- ? The topmost node is called the root, and the other nodes are subordinates of the root.
- ? The **Network Data Model** is an extension of the hierarchical model and allows more complex relationships between data entities.
- ? It organizes data as a **graph** where multiple parent-child relationships can exist, and records can have more than one parent.
- ? This is done through sets of relationships, which are used to form networks of data.

- ? The **Object-Oriented Data Model** (OODM) in Database Management Systems (DBMS) is a data model that integrates the principles of object-oriented programming (OOP) with the traditional database concepts.
- ? Object-oriented database management systems (OODBMS) combine database capabilities with object-oriented programming language capabilities.
- ? This model allows databases to store objects, which are instances of classes, in a way that mirrors the behavior of objects in object-oriented programming languages like Java, C++, and Python.

- ? The most popular data model in use today is the **relational data model**.
- ? Other traditional models, such as **hierarchical data models** and **network data models**, are still used in industry mainly on mainframe platforms.
- ? However, they are **not commonly used due to their complexity**.
- ? These are all referred to as **traditional models** because they preceded the relational model.

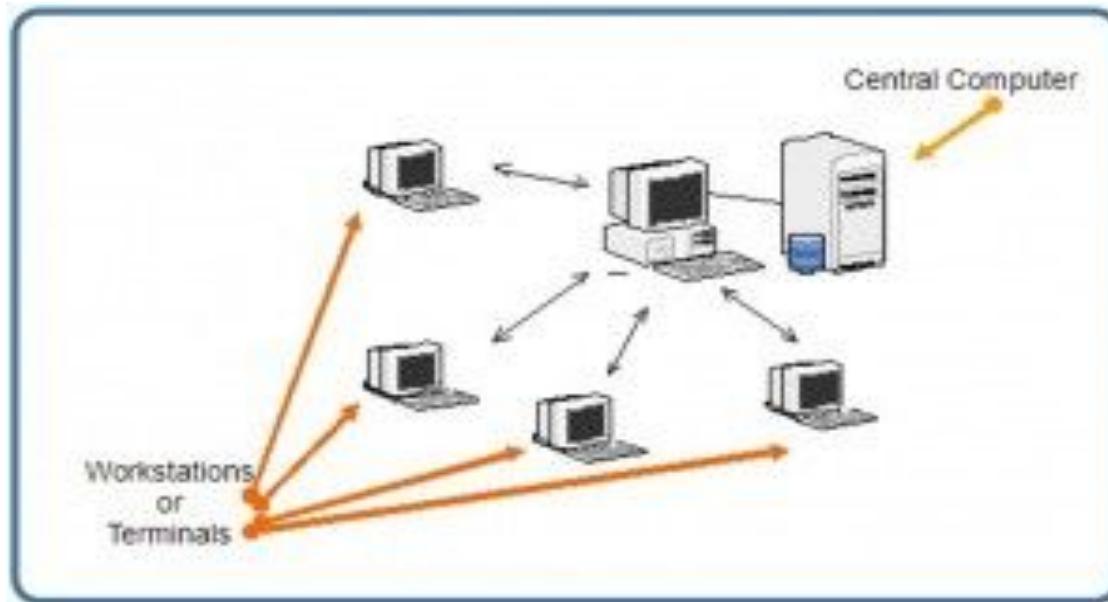

Classification Based on User Numbers

- ? Single-user database system
 - ? Multi-user database system
- ? A DBMS can be classified based on the number of users it supports.
- ? It can be :
- ? **Single-user** database system, which supports one user at a time, or
 - ? It typically serves smaller-scale applications where only one individual interacts with the database, such as a personal application or standalone system.
 - ? **Multiuser** database system, which supports multiple users concurrently.
 - ? Unlike single-user systems, multi-user systems enable many users to interact with the database concurrently without interfering with each other's operations.

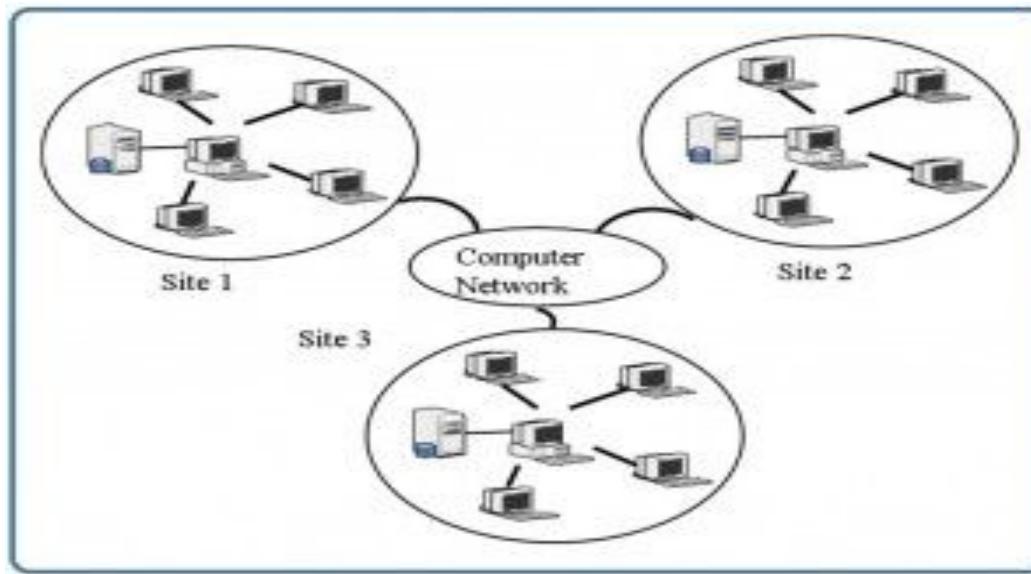

Classification Based on Database Distribution

- ? Centralized systems
- ? Distributed Systems

With a **centralized database system**, the DBMS and database are stored at a single site that is used by several other systems too.

In a **distributed database system**, the actual database and the DBMS software are distributed from various sites that are connected by a computer network.

- ? Distributed database system:
 - ? Homogeneous systems
 - ? Heterogeneous systems

Homogeneous distributed database systems

- ? Homogeneous distributed database systems use the **same DBMS software from multiple sites.**
- ? ***Data exchange between these various sites can be handled easily.***
- ? For example, **library information systems** by the same vendor may use the same DBMS software which allows easy data exchange between the various library sites.

Heterogeneous distributed database systems

- ? In a heterogeneous distributed database system, **different sites might use different DBMS software**, but there is ***additional common software to support data exchange between these sites.***
- ? For example, the various **library database systems** use the same machine-readable cataloguing (MARC) format  to support library record data exchange.

Classification Based on Cost:

1. Low cost DBMS – The cost of these systems vary from \$100 to \$3000.
2. Medium cost DBMS – Cost varies from \$10000 to \$100000.
3. High cost DBMS –Cost of these systems are usually more than \$100000

Classification Based on Access:

1. Sequential access – One after the other.
2. Direct access
3. Inverted file structures

Classification Based on the usage:

- ? Online transaction processing(OLTP) DBMS
- ? Online analytical processing(OLAP) DBMS
- ? Big data and analytics DBMS
- ? XML DBMS, GIS DBMS, Sensor DBMS, Mobile DBMS, Open source DBMS

RELATIONAL MODEL CONCEPTS

- ? A Relation is a mathematical concept **based on the ideas of sets**
- ? The model was first proposed by Dr. E.F. Codd of IBM Research in 1970 in the following paper: "A Relational Model for Large Shared Data Banks," Communications of the ACM, June 1970
- ? The above paper caused a **major revolution** in the field of database management and earned Dr. Codd the coveted ACM Turing Award

INFORMAL DEFINITIONS

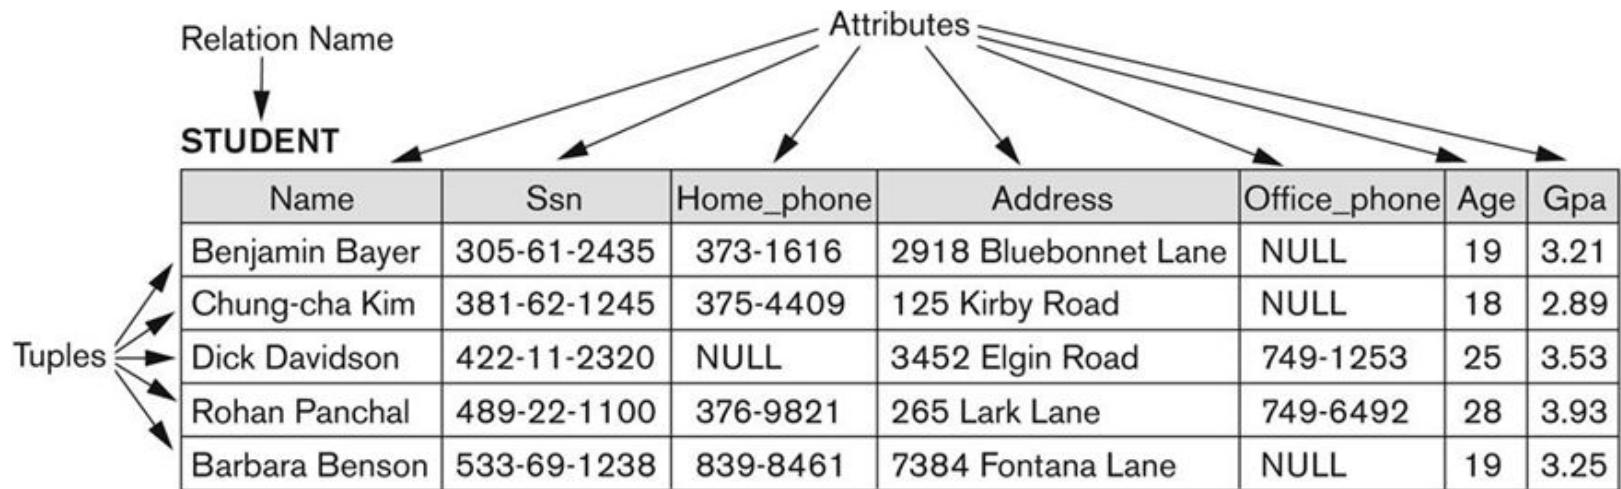

RELATION: A table of values

- A relation may be thought of as a set of rows.
- Each row represents a fact that corresponds to a real-world entity or relationship.
- Each row has a value of an item or set of items that uniquely identifies that row in the table.
- Each column typically is called by its column name or column header or attribute name.

Key of a Relation: Called the key

- In the STUDENT table, SSN is the key
- Sometimes row-ids or sequential numbers are assigned as keys to identify the rows in a table

The attributes and tuples of a relation STUDENT.

FORMAL DEFINITIONS

- The **Schema** (or description) of a Relation:
 - Denoted by $R(A_1, A_2, \dots, A_n)$
 - R is the name of the relation
 - The attributes of the relation are A_1, A_2, \dots, A_n

Example:

CUSTOMER (Cust-id, Cust-name, Address, Phone#)

- CUSTOMER is the relation name
- Defined over the four attributes: Cust-id, Cust-name, Address, Phone#
- Each attribute has a domain or a set of valid values.
- For example, the domain of Cust-id is 6 digit numbers.

- ? A row is called a **tuple**, which is an **ordered set of values**
- ? A **column header** is called an **attribute**
- Each attribute value is derived from an appropriate domain.
- ? The **table** is called a **relation**.
- A relation can be regarded as a set of tuples (rows).
- ? The data type describing the types of values an attribute can have is represented by a domain of possible values.
- ? Each row in the CUSTOMER table is a 4-tuple and consists of four values, for example.

<632895, "John Smith", "101 Main St. Atlanta, GA 30332",
"(404) 894-2000">

- ? A relation is a **set of such tuples (rows)**.
- ? A **domain** has a **logical definition**.
- ? Example: “USA_phone_numbers” are the set of 10 digit phone numbers valid in the U.S.

- The relation is formed over the cartesian product of the sets; each set has values from a domain
- The Cartesian product of two sets A and B is defined to be the set of all pairs (a, b) where $a \in A$ and $b \in B$. It is denoted $A \times B$, and is called the Cartesian product

<table border="1"> <thead> <tr> <th>SID</th> <th>SName</th> </tr> </thead> <tbody> <tr> <td>111</td> <td>Williams</td> </tr> <tr> <td>222</td> <td>Johnes</td> </tr> </tbody> </table>	SID	SName	111	Williams	222	Johnes	<table border="1"> <thead> <tr> <th>C_NO</th> <th>SID</th> </tr> </thead> <tbody> <tr> <td>1000</td> <td>111</td> </tr> <tr> <td>2000</td> <td>222</td> </tr> </tbody> </table>	C_NO	SID	1000	111	2000	222	<p style="text-align: center;">STUDENT \times ENROLLMENT</p> <table border="1"> <thead> <tr> <th colspan="2">STUDENT</th> <th colspan="2">ENROLLMENT</th> <th colspan="4">RESULT</th> </tr> <tr> <th>SID</th> <th>SName</th> <th>C_NO</th> <th>SID</th> <th>SID</th> <th>SName</th> <th>C_NO</th> <th>SID</th> </tr> </thead> <tbody> <tr> <td>111</td> <td>Williams</td> <td>1000</td> <td>111</td> <td>111</td> <td>Williams</td> <td>1000</td> <td>111</td> </tr> <tr> <td>111</td> <td>Williams</td> <td>2000</td> <td>222</td> <td>111</td> <td>Williams</td> <td>2000</td> <td>222</td> </tr> <tr> <td>222</td> <td>Johns</td> <td>1000</td> <td>111</td> <td>222</td> <td>Johns</td> <td>1000</td> <td>111</td> </tr> <tr> <td>222</td> <td>Johns</td> <td>2000</td> <td>222</td> <td>222</td> <td>Johns</td> <td>2000</td> <td>222</td> </tr> </tbody> </table>	STUDENT		ENROLLMENT		RESULT				SID	SName	C_NO	SID	SID	SName	C_NO	SID	111	Williams	1000	111	111	Williams	1000	111	111	Williams	2000	222	111	Williams	2000	222	222	Johns	1000	111	222	Johns	1000	111	222	Johns	2000	222	222	Johns	2000	222

- ? The **degree of a relation** is the **number of attributes n** of its relation schema.
- ? A relation schema R of degree n is denoted by $R(A_1, A_2, \dots, A_n)$
- ? The domain of A_i is denoted by $\text{dom}(A_i)$.

DEFINITION SUMMARY

<u>Informal Terms</u>	<u>Formal Terms</u>
Table	Relation
Column	Attribute/Domain
Row	Tuple
Values in a column	Domain
Table Definition	Schema of a Relation
Populated Table	Extension

CHARACTERISTICS OF RELATIONS

- ? ***Ordering of tuples in a relation r(R):***
 - ? – The tuples are **not** considered to be **ordered**, even though they appear to be in the tabular form.
- ? ***Ordering of attributes in a relation schema***

R (and of values within each tuple):

 - ? – We will consider the **attributes** in R(A₁, A₂, ..., A_n) and the **values** in t=<v₁, v₂, ..., v_n> to be **ordered**.
 - ? ***Values in a tuple:*** All values are considered **atomic** (indivisible). A special **null** value is used to represent values that are **unknown** or **inapplicable** to certain tuples.
 - ? **Multivalued attributes**-Represented by **separate relations** . Ex: A person may have many phone numbers and email addresses.
 - ? **Composite attributes** -Represented by **single component**. Ex. Address. It can be divided into house number, street, city, and state.
